Image: <https://ohmy.disney.com/>

- The processes that produce plant-available nitrogen are biologically mediated
- We must find solutions to minimize losses

Image: <https://www.studyacs.com/>

- Urea-based nitrogen fertilizer products are susceptible to ammonia volatilization

- Ammonia volatilization leads to agricultural losses

Image: <https://homeguides.sfgate.com/>

# Problem

- Urease inhibitors can limit urea hydrolysis for between 7 to 14 days, after which rain, irrigation, or soil mixing would be needed to reduce ammonia volatilization
- But what happens when there is no rain?
- Are there other alternatives?
- $\text{NH}_3 + \text{H}_2\text{O} \rightarrow \text{NH}_4^+ + \text{OH}^-$
- Perhaps something with a high CEC and/or causes a reduction in pH could reduce ammonia volatilization?

- ▶ Humates have been shown to have very high CEC and AEC
- ▶ They can be extracted from any material containing well-decomposed organic matter - soil, coal, composts, etc
- ▶ We tested the hypothesis that amending Urea Ammonium Nitrate (UAN) with a humate could reduce ammonia volatilization

# Methodology

- Land near LeRoy, Sk
- Clay loam soil, pH 8
- Wheat seeded at 135 lbs/ac
- Nitrogen side banded 1.5" deep
- UAN at 90 lbs N/acre
- Treatments replicated thrice:

Untreated UAN

UAN + NBPT (N-(n-butyl) thiophosphoric triamide; 1.6 litres per tonne of UAN)

UAN + humate (600 ml of humate per 76 litres of UAN)

- Other fertilizers: Urea 65 lbs/ac, MAP 73 lbs/ac, KCl 40 lbs/ac

## Development of a simple and affordable method of measuring ammonia volatilization from land applied manures

M. Van Andel, J.S. Warland, P.D. Zwart, B.J. Van Heyst, and J.D. Lauzon

**Abstract:** Quantifying ammonia ( $\text{NH}_3$ ) flux following fertilizer and manure nitrogen (N) application is crucial to develop sound management practices. Traditional methods used for obtaining these measures are expensive, inefficient, or inaccurate. The objective of this study is to develop a method using a passive dosimeter and a semi-open static chamber to provide an economical and simple solution to measure  $\text{NH}_3$  loss following nitrogen application. Dosimeter tubes were commercially developed to measure ammonia exposure, providing a time-weighted average. In this study, chicken manure was applied to short grass and the ppm h reading obtained using the dosimeter ammonia method was calibrated against a reference measure of  $\text{NH}_3$  loss ( $\text{kg N ha}^{-1}$ ) using a wind tunnel and acid trap method. A calibration was developed (Estimated Total Loss ( $\text{kg N ha}^{-1}$ ) =  $(0.217Dw) - (0.034D) + 0.71$ ), which requires the dosimeter (D, ppm h) to be read every 24 h and placed at a height of 0.15 m in the dosimeter chamber, with wind speed (w,  $\text{m s}^{-1}$ ) measured at a height of 0.3 m and averaged over the coinciding time period. This calibration may also be applied where dosimeters are read every 48 h; however, 24 h periods are recommended to achieve the greatest accuracy.

**Key words:** ammonia volatilization, dosimeter ammonia method, semi-open static chambers, calibration.

**Résumé :** Pour élaborer des pratiques de gestion valables, on doit absolument quantifier le flux d'ammoniac ( $\text{NH}_3$ ) consécutif à l'application d'azote (N) sous forme d'engrais chimique ou de fumier. Toutefois, les méthodes usuelles pour le faire sont dispendieuses et manquent d'efficacité ou de précision. Les auteurs voulaient élaborer une méthode reposant sur l'usage d'un dosimètre passif et d'une chambre statique semi-ouverte avec laquelle on quantifierait simplement et de façon économique les pertes de  $\text{NH}_3$  après l'application d'azote. À cette fin, ils ont développé commercialement des éprouvettes dosimétriques ou dositubes qui mesurent l'exposition à l'ammoniac et en donnent une moyenne pondérée dans le temps. Dans le cadre de cette étude, ils ont appliqué du fumier de poulet sur de l'herbe rase et ont étalonné le nombre de ppm par heure établi avec les dositubes d'ammoniac (DA) d'après les pertes de  $\text{NH}_3$  (kg de N par hectare) mesurées dans une soufflerie et avec une technique de piégeage à l'acide. Les auteurs ont ainsi mis au point une formule [perte estimative totale (kg de N par ha) =  $(0.217Dw) - (0.034D) + 0.71$ ] en vertu de laquelle on procède à une lecture des dositubes (D, ppm par heure) toutes les 24 h, à une hauteur de 0,15 m dans la chambre du dositube. La vitesse moyenne du vent (w, en m par seconde) est déterminée à 0,3 m de hauteur pour une période équivalente. Les relevés doivent aussi être effectués aux 48 h.

Dosimeter tubes (#3D, Gastec Corporation, Japan) measure ammonia exposure

The dositube contains purple packing material (sulphuric acid) that turns yellow when it reacts with ammonia (becoming ammonium sulphate)

The scale shows the concentration of  $\text{NH}_3$  over time ( $\text{ppm hr}^{-1}$ )

Tubes are suspended on a stake at a height of 0.15 m above the soil surface

Covered up with a semi-open static chamber immediately after N application

- a round pail with a height of about 26.5 cm and an inner diameter of 19 cm
- Eight 1.27-cm-diameter (1/2 inch) holes were drilled into the top of the pail, and eight 1.27-cm-diameter holes were drilled 4 cm from the bottom of the pail

$$(\text{Estimated Total Loss (kg N ha}^{-1}\text{)}) = (0.217Dw) - (0.034D) + 0.71$$

Where D = Dosimeter reading

W = wind speed

(w,  $\text{m s}^{-1}$ ) measured at a height of 0.3 m and averaged over the coinciding time period

## Results and discussion

- Ammonia volatilization was slow for the first 2 weeks (nothing was picked up in the dosimeters)
- Land received no rain

Average rate of ammonia volatilization over 32 days

Estimated loss of N as ammonia after 32 days

- ***Any story worth telling is worth telling twice***  
- Rafiki

Image: [disney.fandom.com](https://disney.fandom.com)

# Laboratory experiment

- 1 kg of soil (pH 7.03)
- Same rate of humate as in the field (600 ml of humate per 76 litres of UAN)
- Applied 1 ml of UAN (or UAN + humate); 3 reps
- Moistened to about 60% of field capacity

- Containers were fit with dosimeters and covered
- Monitored for 5 hours

# What is the mechanism?

### Effect of humic acid on ammonia volatilization from some calcareous soils

Hayfaa J. Al-Tameemi, Nawal I. Ashoor, Suhailah J. Al-Auqbi

Department of Soil Science and Water Resources, College of Agriculture, University of Basrah, Basrah, Iraq. Corresponding author: H. J. Al-Tameemi, haifa.jasim@yahoo.com

**Abstract.** The objectives of this study were to compare the effect of three rates of humic acid (0, 2.5 and 5.0 g kg<sup>-1</sup> soil) and N-urea (0, 60 and 120 mg N kg<sup>-1</sup> soil) and mixtures of them on NH<sub>3</sub> loss (volatilization) from two calcareous soils (Abul-Khasseb, silty clay soil, and Zubair, loamy sand soil). The use of humic acid significantly reduced NH<sub>3</sub> loss and increased exchangeable NH<sub>4</sub><sup>+</sup> in both studied soils. The high total acidity of humic acid made the best in reducing N loss after incubation. Zubair soil showed more N loss than Abul-Khasseb soil due to their physical and chemical characteristics. The soil content of NH<sub>4</sub><sup>+</sup> and NO<sub>3</sub><sup>-</sup> increased significantly in both studied soils with increasing N rates. It can conclude that, humic acid, in general have great ability in controlling NH<sub>3</sub> loss and retaining NH<sub>4</sub><sup>+</sup> in calcareous soils. It could be an economical efficient, practical and easiest way to control N loss.

**Key Words:** N-urea, N loss, urea fertilizer, ammonium, nitrate.

**Introduction.** Ammonia volatilization is a major pathway for N loss from surface-applied urea (Cai et al 2002; Prasertsak et al 2001). Volatilization losses can occur in calcareous soils due to high pH and NH<sub>4</sub><sup>+</sup> in the microsite where urea granules are dissolved and hydrolyzed (Siva et al 1999; Fan & Mackenzie 1993). Under normal conditions ammonium (NH<sub>4</sub><sup>+</sup>), hydroxyl (OH<sup>-</sup>) and carbonate (CO<sub>3</sub><sup>2-</sup>) ions are produced rapidly (1 or 2 days) after surface application of urea by urease (Zhengping et al 1991). This leads to the accumulation of NH<sub>4</sub><sup>+</sup> which simultaneously increases the soil pH surrounding the application area or near the urea granule (Zaman et al 2007). The increase of OH<sup>-</sup>, HCO<sub>3</sub><sup>-</sup> and NH<sub>4</sub><sup>+</sup> concentrations through this process plays a significant role in the rapid loss of nitrogen.

There are many factors involved in NH<sub>3</sub> volatilization, which can be grouped into soil (e.g. pH, CEC), environment (e.g. temperature, humidity) and management (e.g. surface application of fertilizer, drilling). A number of studies with different soils have reduced NH<sub>3</sub> losses (Fan & Mackenzie 1993; Al-Kanani et al 1990; Katyal 1998; Zaman et al 2007). Acidic materials alone, organic and inorganic mixture of acidic materials and additives could reduce N losses by 60, respectively (Lethbride & Burns 1976; Al-Kanani et al 1990; Fan & Mackenzie 2007).

In some studies, acidic materials such as humic acid and triple superphosphate have been used to reduce ammonia loss from surface applied urea (Fan & Mackenzie 1993; Ahmed et al 2006). These acidic materials lower the soil microsite around the fertilizer, reduce the hydrolysis of urea thus reducing the loss. Humic acid has high total acidity (CEC) aid to retain NH<sub>4</sub><sup>+</sup> and NO<sub>3</sub><sup>-</sup> which is useable from of nitrogen (Fan & Mackenzie 1993; Ahmed et al 2006). The aim of this study was to evaluate the effectiveness of humic acid in reducing N loss from urea fertilizer added to two calcareous soils as well as to investigate the ability of humic acid to retain NH<sub>4</sub><sup>+</sup>, or reduce soil pH.

**Material and Method.** The study was conducted on two calcareous soils from Basrah governorate (Abul-Khasseb and Zubair-Barjesia). The soil samples taken at 0 - 30 cm depth were air dried and ground to pass 2 mm sieve. The selected chemical and physical

**Abstract**

Humic acids (HAs) play an important role in the global nitrogen cycle by influencing the distribution, bioavailability, and ultimate fate of organic nitrogen. Ammonium oxidation by autotrophic ammonia-oxidizing bacteria (AOB) is a key process in ecosystems and is limited, in part, by the availability of ammonium. In this study, we investigated the effect of HAs on AOB in microcosms by degraded lignite humic acids, and found that AOB population increased after urea and HA addition. AOB activity (measured by the universal bacterial probe) increased after urea and HA addition, and fluctuated back to baseline after 1 week.

Reduction of pH?  
Increase in CEC?  
Change in microbial composition?

## pH and CEC of experimental soils

# Conclusions and recommendations

- Ammonia volatilization can put crops behind early in the season
- Amending urea-based fertilizers with humic substances may provide some benefit
- Mechanisms need to be further studied
- Effect on nitrate leaching needs to be evaluated
